(54) Title: DRILL BITS

(57) Abstract: An expandable drill bit (10) comprises a body (14) for mounting on a support string and two roller cutters (12, 13) mounted on the body (14). The cutters (12, 13) are movable between a smaller diameter first configuration and a larger diameter second configuration. In one embodiment the bit (10) is adapted to drill with the cutters (12, 13) in both the first and second configurations.

WO 02/01037 A1

DRILL BITS

This invention relates to drill bits. Aspects of the invention relate to both fixed and expandable drill bits.

Deep bores, for example, as utilised to access subsurface hydrocarbon-bearing formations, are conventionally drilled using drill bits mounted on the end of a string of drill pipe, the drill pipe being rotated from surface. It is also known to drill bores using drill bits driven by downhole motors, and to mount drill bits on relatively flexible coil tubing. There are currently two main drill bit forms in common usage, that is roller cone bits and fixed cutter bits, the former cutting primarily by a crushing action and the latter relying primarily upon a shearing action.

In drilling deep bores, it is common to drill a section of bore and then line or case the bore before drilling further. Using a conventional fixed diameter bit, any subsequent drilling produces a relatively small diameter bore; the drill bit must be able to pass down through the cased section of bore, and must therefore be of smaller diameter than the casing. Such a loss of diameter may be minimised by, for example, using a bi-centre bit, or by providing an expandable bit. However, use of a bi-centre bit generally must be preceded by drilling a short

pilot hole which must then be under reamed to accommodate the bit. Also, although numerous expandable bits have been proposed, these are of complex construction and the applicant is unaware of any such bit in current commercial  
5 usage.

It is among the objectives of embodiments of the present invention to obviate or mitigate such disadvantages, and one aspect of the invention relates to an improved expandable drill bit arrangement.

10 According to a first aspect of the present invention, there is provided an expandable drill bit comprising:

a body for mounting on a support string; and

at least two roller cutters mounted on the body, the cutters being movable between a smaller diameter first configuration and a larger diameter second configuration.  
15

Thus, the bit may be run into a cased bore, and through bore restrictions, while in the first configuration, and then extended to the second configuration to cut a bore of greater diameter than the casing or bore restrictions. In certain embodiments the  
20 drill bit may also be utilised for back-reaming, that is pulling the bit back through a bore and enlarging the bore diameter.

Other aspects of the invention relate to methods of  
25 drilling a bore of greater diameter than a bore restriction above the drilling location utilising an expandable roller

cutter drill bit.

Preferably, two cutters are provided. Most preferably, inner ends of the cutters overlap, such that the cutting area swept by the cutters is, in at least some configurations, a complete circle. In other embodiments, 5 three or more cutters may be provided.

Preferably, the bit is adapted to drill with the cutters in both the first and second configurations. In one embodiment, this permits the bit to be utilised to 10 drill a smaller diameter pilot hole with the cutters in the first configuration and then to extend the pilot hole to a larger diameter with the cutters in the second configuration. The bit may also be adapted to drill with the cutters in intermediate configurations, between the 15 first and second configurations, to drill bores of intermediate diameters. For such embodiments, it is preferred that the faces of the cutters for contact with the rock always describe a complete swept circle as the bit is rotated; otherwise, in some configurations the cutters 20 will, for example, describe an annular area leaving a central area of uncut rock. Alternatively, the bit may be adapted to drill only with the cutters in the second configuration, or only in extended configurations. As, with these latter embodiments, there is no requirement for 25 the cutters to operate in the first configuration, the cutter configuration may be optimised for drilling

relatively large diameter bores.

Preferably, the cutters are in the form of cones. The cones may be tapered, barrellled, or define some other profile. Most preferably, the cones each define a shoulder and a maximum diameter portion intermediate the cone ends:  
5 In preferred embodiments, the cones are arranged such that the cone maximum diameter portion cuts the diameter of the bore.

Each cutter may be rotatable about its main axis, or  
10 may be rotatable about an offset axis to provide for eccentric cutter motion and a "hammer" cutting effect.

Preferably, the cutter length is at least 50% of the body diameter, and the cutter length may be equal to or greater than the body diameter.

15 The cutters may be provided with any appropriate cutting structures, inserts or facings, including tungsten carbide buttons or blocks, poly crystalline diamond compacts or natural diamond, secured or fixed to the cutters by any appropriate method. The cutting structures  
20 may be arranged in parallel rows or indeed any appropriate pattern or random placement.

Preferably, the cutters are arranged to allow intermeshing of the cutting structures on each cone.

Preferably, the cutters are rotatable around a non-  
25 radial axis. The cutters thus provide a shearing or scooping action as the bit is rotated. The cutter axes are

preferably parallel, but may be convergent or divergent. Preferably, the each cutter axis lies in a plane which is non-perpendicular to the body axis, although the cutter axes may be perpendicular to the body axis to provide a less aggressive cutting action.

Preferably, the cutters are mounted on arms pivotally mounted to the body. The cutter axes may lie in a plane which is non-parallel to the bit body lateral axis which is perpendicular to the pivot axis or axes. This facilitates provision of a circular swept cutting area, and the avoidance of an uncut area as the cutters are extended. In other embodiments, particularly when the bit is capable of drilling in both first and second configurations, the cutter axes may lie in a plane which is parallel to the bit body axis; any area left unswept with the cutters in the second configuration will have already been removed by the drilling of a pilot hole with the cutters in the first configuration. The arms may be mounted on a common pivot axis.

Preferably, the cutters are supported at both ends, and most preferably provided with bearings and seals at both ends, and are thus likely to be more robust than a conventional roller cone bit, in which the cutters are supported at only one end.

Preferably, the bit includes means for actuating the cutters between the first and second configurations. The

means may be actuated by any appropriate method, including mechanical actuation, but is preferably fluid pressure actuated, and may include a drilling fluid actuated piston arrangement, or some other arrangement such as a bore restriction or a profile adapted to catch a ball or other restriction. Where a piston arrangement is utilised, two or more "intensifier" pistons may be provided, to increase the available applied forces. Most preferably, the means may be selectively operated, for example by use of a cam track and follower arrangement, and may be selectively locked or held in one or both configurations. Most preferably, the means is adapted to selectively positively retract the cutters from the second configuration. The actuating means may include a spring or other arrangement such that the means is biased to urge the cutters to assume the first configuration.

The body or other components, for example, cone shafts, may define a lubricant reservoir for supplying lubricant to bearings and other moving parts provided in the bit, and the reservoir may include a drilling fluid actuated piston or other mechanism which serves to pump lubricant to the required locations.

The body may define jetting nozzles, which nozzles may be selectively opened or closed depending on the configuration of the cutters, thus altering the back pressure produced by the bit, and providing an indication

at surface of the cutter configuration. The nozzles may direct fluid onto the cone surfaces, and towards the bottom or sides of the bore.

The bit may define cutting faces in addition to those provided by the cutters, for example the body or cutter supporting arms may define a cutting faces.

Many of these various preferred features of the first aspect of the invention may also be utilised to advantage in a fixed diameter drill bit or in bits not in accordance with the various aspects of the invention set out above, and bits including selected ones of these features, and the features of the dependent claims set out below, provide further aspects of the present invention.

These and other aspects of the present invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a part-sectional view of a drill bit in accordance with an embodiment of the present invention, shown in a first configuration;

Figure 2 is a view from below of the drill bit of Figure 1;

Figure 3 is a part-sectional view of the drill bit of Figure 1 in a second configuration;

Figure 4 is a view from below of the drill bit of Figure 3;

Figure 5 is a part-sectional view of a drill bit in

accordance with another embodiment of the present invention, shown in a first configuration;

Figure 6 is a view from below of the drill bit of Figure 5;

5        Figure 7 is a part-sectional view of the drill bit of Figure 5 in a second configuration; and

Figure 8 is a view from below of the drill bit of Figure 7.

The reference is first made to Figure 1 of the drawings, which illustrates a drill bit 10 in accordance  
10        with a preferred embodiment of the present invention. As will be described, the bit 10 comprises conical roller cutters 12, 13 which are movable between a smaller diameter first configuration, as shown in Figures 1 and 2, and a  
15        larger diameter second configuration, as shown in Figures 3 and 4. This allows the bit 10 to pass through bore restrictions and then be extended to cut larger diameter bores, as will be described.

The bit 10 comprises a generally cylindrical body 14  
20        adapted for mounting on the end of a drill string. As illustrated, the body 14 is provided with a box-type connector 16 for engaging a pin-type connector on the end of a drill string. The cutters 12 are mounted on the lower end of the body 14 by respective pivoting arms 18, 19. The  
25        lower end of the body 14 is in the form of an extension 20 which provides mounting for a pivot pin 22 on which the

arms 18, 19 are mounted, the arms each featuring a clevis-like arrangement such that the arms each engage the pin at two spaced locations on opposite sides of the extension 20. The pivot pin 22 is arranged such that the pivot axis 24 of  
5 the arms 18, 19 intersects and lies at right angles to the body axis 26.

The cutters 12, 13 each define a maximum diameter portion 28 intermediate the cutter ends, and define a shoulder 30 between the portion 28 and the cutter outer  
10 end. The cutters 12, 13 are mounted on shafts (not shown) extending along the respective cutter axes 32, 33, the shafts being supported at both ends by fingers 34, 35 extending from the ends of the arms 18, 19. It will be noted from Figure 1 that the cutter axes 32 lie in a plane  
15 which is at an acute angle A to the body axis 26, and from Figure 2 that the cutter axes 32, 33 lie in mutually parallel vertical planes.

The bit 10 is adapted to be capable of cutting in the first configuration, and the swept area of the cutters 12,  
20 13 is illustrated by chain dotted line B in Figure 2. It will be evident that the diameter of the swept circle is defined by the cutter maximum diameter portions 28, which will cut a bore of greater diameter than the bit body 14.

The cutters 12, 13 are moved between the first  
25 configuration, as illustrated in Figures 1 and 2, and the second configuration, as illustrated in Figures 3 and 4, by

application of drilling fluid pressure, as will now be described. The body is partially hollow and defines an axial generally cylindrical chamber 36 which accommodates an annular piston 38 mounted around a central locating sleeve 40, the lower end of the sleeve being fixed to the body 14. The portion of the chamber 36 below the piston 38 accommodates a spring 42, for urging the piston 28 to an upper position, and this portion of the chamber is also in communication with the body exterior, via vent port 44.

The piston 28 is movable in response to fluid pressure within the body 14, however the axial movement of the piston 38 is governed by a cam profile 42 formed in the outer surface of the piston and which co-operates with a cam pin 48 mounted in the body wall. Thus, as the fluid pressure within the body is cycled, the piston 38 will move axially and rotationally as permitted by the inter-engagement of the cam profile 46 and the pin 48, the accompanying rotation of the piston 38 being facilitated by the provision of a bearing 50 between the lower end of the piston 38 and the spring 42.

The cam profile 46 is arranged such that the piston 38 will only advance to extend the cutters 12, 13 at selected points in a pressure cycle. On other occasions the cam profile 46 is arranged to limit the forward axial movement (to location C) to prevent extension of the cutters, thus allowing circulation of drilling fluid, and drilling, while

the cutters 12, 13 remain in the first configuration. However, when the cam profile 46 is in a selected orientation, the piston 38 may advance to the position as illustrated in Figure 3, to fully extend the cutters 12, 13. In other embodiments of the invention the cam profile may be selected to allow the cutters 12, 13 to extend in incremental steps, that is the cutters 12, 13 may be positively located in intermediate positions, between the first and second configurations.

10 In its advanced position, the lower end of the piston 38 engages the head of rod 52 which extends into the body chamber 36, like the piston 38 the rod 52 being biased by a spring 54 towards a cutter retracted configuration. The rod 52 extends through the body 14 to engage a skirt 56  
15 mounted around the body extension 20. The skirt 56 features two axially extending lugs 58 (only one shown) on either side of the body extension, each lug 58 carrying a cam pin 60 located in a cam slot 62 in the upper end of a respective cutter mounting arm 18, 19.

20 Thus, when permitted by the cam profile 46, advancement of the piston 38 produces corresponding movement of the rod 52 and the skirt 56. As the sleeve cam pins 60 are offset from the pivot axis 24, axial movement of the pins 60 causes the arms 18, 19 to pivot outwardly to  
25 move the cutters 12, 13 towards the larger diameter second configuration as illustrated in Figures 3 and 4. However,

to minimise unnecessary stresses of the pins 60, the pins 60 do not travel to the ends of the slots 62. The provision of cam slots 62 in the arms 18, 19 also provides the advantage that the arms will be positively retracted, in response to the action of the spring 54, when the fluid pressure drops to allow the rod 52 to retract into the body 14.

It will also be noted that the blind end of the slots 62 includes a short extension 63 lying perpendicular to the remainder of the slot, and which extension 63 lies longitudinally of the bit 10 when the cutters 12, 13 are fully extended. Thus, the movement of the skirt 56 corresponding to the end of the stroke of the piston 38 does not induce any corresponding rotation of the arms 18, 19, rather this movement brings the skirt 56 into engagement with an opposing face 66 defined by the arms 18, 19. These faces 66 act as stops and serve to transfer forces to the skirt 56 from the arms 18, 19, and reduce the load transferred to the pivot pin 22 (Figure 3 shows the face 66 and the end of the skirt spaced apart). Furthermore, the faces serve to lock the cutters 12, 13 in the extended configuration, which is especially useful if the bit is configured to allow back reaming.

As the skirt 56 is pushed downwardly, drilling fluid ports 64 are opened, allowing fluid to flow from the body. This results in a drop in the fluid pressure within the

13

body, which pressure drop is detectable at surface, providing an indication that the cutters 12, 13 have been moved to the second configuration. If desired, a number of outlet ports may be provided behind the skirt 56, which  
5 ports are opened in sequence as the skirt 56 advances as the cutters 12, 13 are moved between the first and second positions. Thus, the resulting pressure drops may be utilised as an indicator of the degree of extension of the cutters 12,13. Further, the flow of fluid from the ports  
10 64 also tends to flush cutting from behind the skirt 56, preventing jamming of the skirt 56 when the cutters are retracted. In addition, prior to the skirt 56 moving downwardly, fluid pressure acts on the skirt via the ports 64, the skirt 56 acting as a piston and facilitating  
15 initial extension of the cutters 12, 13.

The arms 18, 19 define faces 66 adapted to engage the body extension 20 when the arms 18, 19 are in the fully extended position. The engagement between the faces 66 and the body extension 20 limits the travel of the arms 18, 19,  
20 and also serves to relieve some of the stress applied to the pivot pin 22 and the arm actuating arrangement when weight is applied to the bit 10 during drilling.

In use, the bit 10 may be used, for example, to drill a section of bore below a previously cased bore section.  
25 In this event, the bit 10 is selected to be of smaller diameter than the casing internal diameter, to allow the

bit 10 to be run into the bore. On reaching the lower end of the cased bore section, drilling fluid is pumped through the supporting string into the bit 10, where it exits the bit through various jetting nozzles (not shown), and the string and bit 10 are rotated from surface. The cutters 12, 13 rotate around the end face of the bore, crushing the rock on the face, which is then removed by the drilling fluid. In this manner, the bit 10 may be utilised to drill a pilot bore. The bit 10 may then be pulled back to just below the end of the cased bore section, and the drilling fluid pressure cycled such that the piston 28 is rotated to a position where the cam profile 46 permits the piston 38 to fully extend. The drilling fluid pressure is increased such that the piston 38 is moved downwardly against the action of the springs 42, 54, and the cutters 12, 13 are urged towards the extended second configuration. The cutters 12, 13 may be unable to be fully extended immediately, however if the bit 10 is rotated the cutters 12, 13 may cut radially outwardly, until the cutters 12, 13 achieve their maximum extension. The bit 10 may then be advanced axially, and in this configuration the cutters 12, 13 will cut an annular area D, to extend the diameter of the existing pilot hole.

It will be apparent to those of skill in the art that the arm and cutter configuration may be varied to provide different cutting configurations. However, where it is

desired to support the cutters at both ends, care is necessary to ensure that the fingers 34, 35 do not foul the bore wall, and lie within the swept area of the cutters 12, 13.

5           Reference is now made to Figures 5, 6, 7 and 8 of the drawings, which illustrate a drill bit 110 in accordance with another embodiment of the present invention. The bit 110 shares many features with the bit 10 described above. Accordingly, in the interests of brevity, features of  
10           structure and operation common to both bits 10, 110 will not be described again in great detail, and corresponding features of the bit 110 will be identified with the same reference numerals, prefixed by a "1".

          The bit 110 is intended primarily to be used for  
15           drilling with the cutters 112, 113 in the second configuration (as shown in Figures 7 and 8). Thus, the cutters 112, 113 may have a longer profile, and the cones axes 132, 133 are located in planes which are non-parallel to the bit body lateral axis which is perpendicular to the  
20           arm pivot axis. However, the cutter inside edges lie on this bit body lateral axis, and move along this axis as the cutters 112, 113 are extended. This ensures that the swept area of the cutters 112, 113 is a complete circle, and there is no area left uncut between the cutters 112, 113.

25           The bit 110 also features a simplified piston arrangement, in that there is no cam arrangement for

controlling movement of the piston 128: the piston 128 simply moves axially in response to changes in drilling fluid pressure.

It will be apparent to those of skill in the art that the above-described embodiments are merely exemplary of the present invention, and that various modifications and improvements may be made thereto, without departing from the scope of the present invention. In particular, many features of the expandable bits as described above may also be utilised in a fixed diameter bit. Also, bits made in accordance with the various aspects of the present invention may be configured to permit the bits to be used for back reaming. For such bits, it is desirable that the cutters may be positively retained in the second configuration, as is that case in the first described embodiment of Figures 1 to 4. In addition or as alternative to providing the arms with a locking face 66 to engage the skirt 56, the skirt and arms may feature cooperating profiles, such as castellations or lugs.

CLAIMS

1. An expandable drill bit comprising:  
a body for mounting on a support string; and  
at least two roller cutters mounted on the body, the  
5 cutters being movable between a smaller diameter first  
configuration and a larger diameter second configuration  
and the bit being adapted to drill with the cutters in both  
the first and second configurations.
2. The drill bit of claim 1, wherein two roller cutters  
10 are provided.
3. The drill bit of claim 1 or 2, wherein inner ends of  
the cutters overlap.
4. The drill bit of claim 1, 2 or 3, wherein the bit is  
adapted to drill with the cutters in intermediate  
15 configurations, between the first and second  
configurations.
5. The drill bit of any of the preceding claims, wherein  
faces of the cutters for contact with the rock during

drilling always describe a complete swept circle as the bit is rotated.

6. The drill bit of any of the preceding claims, wherein the cutters are in the form of cones.

5 7. The drill bit of claim 6, wherein the cones each define a shoulder and a maximum diameter portion intermediate the cone ends.

8. The drill bit of claim 7, wherein the cones are arranged such that the cone maximum diameter portion cuts  
10 the diameter of the bore.

9. The drill bit of any of the preceding claims, wherein each cutter is rotatable about its main axis.

10. The drill bit of any of claims 1 to 8, wherein each cutter is rotatable about an offset axis to provide for  
15 eccentric cutter motion and a hammer cutting effect.

11. The drill bit of any of the preceding claims, wherein the cutter length is at least 50% of the body diameter.

12. The drill bit of claim 11, wherein the cutter length is equal to or greater than the body diameter.

13. The drill bit of any of the preceding claims, wherein the cutters are arranged to allow intermeshing of cutting structures on each cutter.

14. The drill bit of any of the preceding claims, wherein  
5 the cutters are rotatable about respective non-radial axes.

15. The drill bit of claim 14, wherein the cutter axes are parallel.

16. The drill bit of claim 14, wherein the cutter axes are non-parallel.

10 17. The drill bit of any of the preceding claims, wherein each cutter axis lies in a plane which is non-perpendicular to the main body axis.

18. The drill bit of any of claims 1 to 16, wherein the cutter axes are perpendicular to the body axis.

15 19. The drill bit of any of the preceding claims, wherein the cutters are mounted on arms pivotally mounted to the body.

20. The drill bit of claim 19, wherein the cutter axes lie in planes which are non-parallel to a main bit body lateral

20

axis which main bit body lateral axis is perpendicular to the pivot axis or axes of the arms.

21. The drill bit of claim 19, wherein the cutter axes lie in planes which are parallel to a main bit body lateral axis, which main bit body lateral axis is perpendicular to the pivot axis or axes of the arms.

22. The drill bit of any of claims 19, 20 or 21, wherein the arms are mounted on a common pivot axis.

23. The drill bit of claim 22, wherein said common pivot axis is defined by a common pivot pin.

24. The drill bit of any of claims 19 to 23, wherein each arm is mounted on a pivot pin and each arm engages the pivot pin at two spaced locations along the length of the pin.

25. The apparatus of any of claims 19 to 24, wherein the arms define support faces and with the roller cutters in the second configuration the support faces engage a part of the body, the faces acting as stops and serving to transfer forces to the body.

26. The drill bit of any of the preceding claims, wherein

the cutters are supported at both ends.

27. The drill bit of any of the preceding claims, wherein the cutters are provided with bearings at both ends.

28. The drill bit of any of the preceding claims, further  
5 comprising means for actuating the cutters between the first and second configurations.

29. The drill bit of claim 28, wherein said means includes a drilling fluid actuated piston arrangement.

30. The drill bit of claim 29, wherein said drilling fluid  
10 actuated piston arrangement comprises at least one piston.

31. The drill bit of claim 30, wherein said at least one piston is annular and defines a throughbore to permit fluid passage therethrough.

32. The drill bit of any of claims 28 to 31, wherein said  
15 means includes a cam track and follower arrangement.

33. The drill bit of claim 32, wherein the cam track is configurable to retain the cutters in the first configuration.

34. The drill bit of claim 32 or 33, wherein the cam track is configurable to retain the cutters in at least one intermediate position between the first and second configurations.

5 35. The drill bit of any of claims 28 to 34, wherein said means is adapted to selectively positively retract the cutters from the second configuration.

36. The drill bit of any of claims 28 to 35, wherein the actuating means includes an arrangement such that the means  
10 is biased to urge the cutters to assume the first configuration.

37. The drill bit of any of claims 28 to 36, wherein the actuating means comprises an axially movable skirt.

38. The drill bit of claim 37, wherein the skirt defines  
15 a piston area which, in use, is exposed to internal body fluid pressure, such that an increase in such pressure tends to extend the skirt, and thus move the cutters towards the second configuration.

39. The drill bit of any of the preceding claims, wherein  
20 the actuating means comprises means for retaining the

cutters in the second configuration.

40. The drill bit of any of the preceding claims, wherein the cutters are configured to permit back reaming when the cutters are in the second configuration.

5 41. The drill bit of claim 37 or 38, wherein the skirt is configured to positively engage with the arms to mechanically lock the cutters in at least one of the second configuration or intermediate configuration.

10 42. The drill bit of any of the preceding claims, wherein the bit defines a lubricant reservoir for supplying lubricant to bearings and other moving parts provided in the bit.

15 43. The drill bit of any of the preceding claims, wherein the body defines jetting nozzles.

44. The drill bit of claim 43, wherein the nozzles are configurable to be selectively opened or closed, depending on the configuration of the cutters.

20 45. The drill bit of any of the preceding claims, wherein the body defines fluid outlets configurable to be selectively opened or closed, depending on the

configuration of the cutters, and wherein, in use, the blade configuration may be determined from surface by monitoring the resulting fluid back pressure.

46. An expandable drill bit comprising:

- 5           a body for mounting on a support string; and  
          at least two roller cutters mounted on the body, the cutters being movable between a smaller diameter first configuration and a larger diameter second configuration.

47. A drilling method comprising the steps:

- 10           providing an expandable drill bit comprising a body and at least two roller cutters mounted on the body, the cutters initially being in a smaller diameter first configuration;

- mounting the drill bit on a drill support and running  
15           the drill bit into a bore of a first diameter;

          moving the cutters to a larger diameter second configuration; and

- drilling the bore with the cutters in the second configuration and with the bit defining a cutting diameter  
20           greater than said first diameter.

48. The method of claim 47, wherein the drill bit is run into a cased bore.

49. The method of claim 47 or 48, further comprising:

drilling a smaller diameter pilot hole with the cutters in the first configuration; and then

5 extending the pilot hole to a larger diameter by drilling with the cutters in the second configuration.

50. The method of any of claims 47, 48 or 49 further comprising cutting rock while the cutters move from the first configuration to the second configuration.

51. A drill bit comprising:

10 a body for mounting on a support string; and  
at least two roller cutters mounted on the body wherein inner ends of the cutters overlap.

52. The drill bit of claim 51, wherein the cutter length is at least 50% of the body diameter.

# INTERNATIONAL SEARCH REPORT

Intern: Application No  
PCT/GB 01/02858

<b>A. CLASSIFICATION OF SUBJECT MATTER</b> IPC 7 E21B10/34		
According to International Patent Classification (IPC) or to both national classification and IPC		
<b>B. FIELDS SEARCHED</b> Minimum documentation searched (classification system followed by classification symbols) IPC 7 E21B		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched		
Electronic data base consulted during the International search (name of data base and, where practical, search terms used) EPO-Internal, WPI Data		
<b>C. DOCUMENTS CONSIDERED TO BE RELEVANT</b>		
Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 4 904 119 A (LEGENDRE YVES ET AL) 27 February 1990 (1990-02-27)  column 4, line 35 - line 44	1-3, 9, 10, 14-16, 18, 19, 26, 28, 35, 39, 40, 46-49, 51
X	GB 838 833 A (ARCHER WILLIAM KAMMERER) 22 June 1960 (1960-06-22) the whole document	46-48, 51
X	US 4 189 185 A (JOHNSON GARY R ET AL) 19 February 1980 (1980-02-19) column 3, line 52 - column 4, line 14	46, 47
<input type="checkbox"/> Further documents are listed in the continuation of box C. <input checked="" type="checkbox"/> Patent family members are listed in annex.		
* Special categories of cited documents : *A* document defining the general state of the art which is not considered to be of particular relevance *E* earlier document but published on or after the international filing date *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified) *O* document referring to an oral disclosure, use, exhibition or other means *P* document published prior to the international filing date but later than the priority date claimed *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art. *&* document member of the same patent family		
Date of the actual completion of the international search  31 August 2001		Date of mailing of the international search report  06/09/2001
